## 1 Checking periodically perturbed free energy

To check that the configuration force matches with the energy, we check the energy for a uniform configuration first, and then for a small perturbation. The latter check gives an estimate for the configuration force by the functional Taylor series expansion:

$$F(Q + \delta Q) = F(Q) + \int_{\Omega} \left( \frac{\delta F}{\delta Q} \Big|_Q : \delta Q \right) dV + \mathcal{O}(|\delta Q|^2) \quad (1)$$

with

$$\frac{\delta F}{\delta Q} = \frac{\partial f}{\partial Q} - \nabla \cdot \frac{\partial f}{\partial(\nabla Q)} \quad (2)$$

Since this holds for an arbitrary functional  $F$ , and also for an arbitrary (small) perturbation  $\delta Q$ , it's probably true that:

$$f(Q + \delta Q) = f(Q) + \left( \frac{\partial f}{\partial Q} - \nabla \cdot \frac{\partial f}{\partial(\nabla Q)} \right) : \delta Q + \mathcal{O}(|\delta Q|^2) \quad (3)$$

for each component of the free energy  $f$ . For the example we test, we take  $Q$  to be:

$$Q = S_0 \begin{bmatrix} \frac{2}{3} & 0 & 0 \\ 0 & -\frac{1}{3} & 0 \\ 0 & 0 & -\frac{1}{3} \end{bmatrix} \quad (4)$$

with

$$\delta Q = S_0 \begin{bmatrix} 0 & \epsilon \sin kx & 0 \\ \epsilon \sin kx & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (5)$$

This corresponds (to first order) to a perturbation of the director so that the total configuration  $(Q + \delta Q)$  is a uniform- $S$  configuration with director  $\mathbf{n} = (1, \epsilon \sin kx, 0)$ .

Here, the nondimensional free energy is given by:

$$F = \int_{\Omega} \left( -\frac{1}{2} \alpha Q : Q + (\log 4\pi - \log Z + \Lambda : (Q + \frac{1}{3} I)) + \frac{1}{2} |\nabla Q|^2 \right) dV \quad (6)$$

Then we can calculate  $F(Q)$  partially analytically and partially numerically. Of course the elastic part is zero, and we calculate:

$$-\frac{1}{2} \alpha Q : Q = -S_0^2 \frac{\alpha}{3} = -1.2153600266666669 \quad (7)$$

with  $S_0 = 0.6751$  and  $\alpha = 8.0$ . Further, we can calculate numerically (see `calc_lambda` program with `generate_periodic_Q_tensors.py`)  $\Lambda$  and  $Z$  for  $S_0 = 0.6751$ :

$$Z = 3.87017170996747$$

$$\Lambda = \begin{bmatrix} 3.6005952163635766 & 0 & 0 \\ 0 & -1.8002976081817883 & 0 \\ 0 & 0 & -1.8002976081817883 \end{bmatrix} \quad (8)$$

Then we may calculate  $F$  by multiplying this energy density by the size of the domain. The uniform configuration check is then just to compare that number with the energy output from the simulation for a uniform configuration with the same  $S_0$  and  $\alpha$  values and domain size. Calculating the energy density from the mean-field interaction gives:

$$f_{\text{entropy}} = 3.60848720197831 \quad (9)$$

Running the simulation and calculating the free energy over the domain gives:

$$F_{\text{mean field}} = -11.99497833 \quad (10)$$

and calculating out the energy density from the entropy term gives:

$$F_{\text{entropy}} = 35.61419603 \quad (11)$$

Comparing these values to the energy density multiplied by  $(3.1415926 \times 3.1415926)$  (the domain size) we get similar results.

We may also consider a configuration with a different  $S_0$ -value, just to be sure. Running a similar calculation with  $S_0 = 0.5$ , we get the following values for  $\Lambda$  and  $Z$ :

$$Z = 1.8088523960817302$$

$$\Lambda = \begin{bmatrix} 2.323990879382531 & 0 & 0 \\ 0 & -1.1619954396912653 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (12)$$

Then the entropy and mean field part of the free energy density is given by:

$$f_{\text{entropy}} = 3.100327077782174$$

$$f_{\text{mean field}} = -\frac{2}{3} \quad (13)$$

Both of these correspond with the energy densities written to the vtu file.

The configuration force, which is exactly the functional derivative of the free energy, is given by:

$$\frac{\delta F}{\delta Q} = -\alpha Q + \Lambda - \nabla^2 Q \quad (14)$$

We need to evaluate this with the unperturbed  $Q$ -tensor – since this is just a uniform configuration, the elastic term will be zero. However, if we explicitly calculate it we find that:

$$\left. \frac{\delta F}{\delta Q} \right|_Q : \delta Q = 0 \quad (15)$$

Hence, we actually can't get any information out of this particular perturbation.

## 2 $S$ -value perturbation

To actually test this, we need to take:

$$\delta Q = \epsilon \sin kx Q \quad (16)$$

Taking  $k = 1$  and  $\epsilon = 0.1$ , we may explicitly calculate (using values previously stated):

$$\left. \frac{\delta F_{\text{mean field}}}{\delta Q} \right|_Q : \delta Q = -\frac{2}{3} S_0 \alpha \epsilon \sin kx = (-0.3600533333333334) \sin kx \quad (17)$$

and

$$\left. \frac{\delta F_{\text{entropy}}}{\delta Q} \right|_Q : \delta Q = \epsilon \sin kx \left( \frac{2}{3} \Lambda_1 - \frac{1}{3} \Lambda_4 + \frac{1}{3} (\Lambda_1 + \Lambda_4) \right) = (0.3600595216363576) \sin kx \quad (18)$$
