

# Twisted disclination velocity

Lucas Myers

February 23, 2024

## 1 Single disclination with added twist

To begin, we consider an isolated disclination which has an added twist. This corresponds to  $\hat{\Omega}$  making an angle  $\beta$  with the tangent vector  $\hat{\mathbf{T}}$ . In our simulations, it appears that the plane which  $\hat{\Omega}$  is confined to is perpendicular to the vector between the two disclinations:

Figure 1: Close-up of a cross-section of a twisted disclination. The axes in the image are different than what is in this note.value(), so take out of the page as  $\hat{\mathbf{x}}$  and upward normal to the cross-sectional plane to be  $\hat{\mathbf{z}}$ . Here  $\beta < 0$  which corresponds to a positive rotation of the director about the  $\hat{\mathbf{x}}$  axis.

For concreteness, we choose  $\hat{\mathbf{T}} = \hat{\mathbf{z}}$  and  $\hat{\Omega} = \sin \beta \hat{\mathbf{y}} + \cos \beta \hat{\mathbf{z}}$ . We note that, to get from a  $+1/2$  wedge disclination to the twist disclination described by this  $\hat{\mathbf{T}}$  and  $\hat{\Omega}$ , one must rotate by  $\beta$  in the  $-\hat{\mathbf{x}}$  direction. Hence, in Cody's parlance we have that:

$$\tilde{\varphi}(z) \hat{\mathbf{q}} = -\beta(z) \hat{\mathbf{x}} \quad (1)$$

From Eq. (7.8) in Cody's thesis, it's clear that the disclination velocity is always zero if we only consider the isotropic elasticity contribution to the equations of motion (since  $\hat{\Omega} \cdot \hat{\mathbf{x}} = 0$ ).

### 1.1 Calculating $L_2$ contribution to velocity

Note that:

$$\hat{\mathbf{n}}_k = \hat{\mathbf{n}}_k + \tilde{\varphi} \mathbf{p}_k \quad (2)$$

with

$$\mathbf{p}_k = (\hat{\mathbf{q}} \times \hat{\mathbf{n}}_k) \quad (3)$$

This gives:

$$\nabla \tilde{\mathbf{n}}_k = \nabla \tilde{\varphi} \mathbf{p}_k \quad (4)$$

Then, from Eq. (7.3) in the thesis we get:

$$Q_{\mu\nu} \approx S_N \left[ \frac{1}{6} \delta_{\mu\nu} - \frac{1}{2} \hat{\Omega}_\mu \hat{\Omega}_\nu + \frac{x}{2a} (\tilde{n}_{0\mu} \tilde{n}_{0\nu} - \tilde{n}_{1\mu} \tilde{n}_{1\nu}) + \frac{y}{2a} (\tilde{n}_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{1\mu} \tilde{n}_{0\nu}) \right] \quad (5)$$

We compute the gradients as follows:

$$\begin{aligned} \partial_k Q_{\mu\nu} \approx \frac{S_N}{2a} & \left[ (\tilde{n}_{0\mu} \tilde{n}_{0\nu} - \tilde{n}_{1\mu} \tilde{n}_{1\nu}) \delta_{kx} + x \partial_k \tilde{\varphi} (p_{0\mu} \tilde{n}_{0\nu} + \tilde{n}_{0\mu} p_{0\nu} - p_{1\mu} \tilde{n}_{1\nu} - \tilde{n}_{1\mu} p_{1\nu}) \right. \\ & \left. + (\tilde{n}_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{1\mu} \tilde{n}_{0\nu}) \delta_{ky} + y \partial_k \tilde{\varphi} (p_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{0\mu} p_{1\nu} + p_{1\mu} \tilde{n}_{0\nu} + \tilde{n}_{1\mu} p_{0\nu}) \right] \end{aligned} \quad (6)$$

and higher order derivatives:

$$\begin{aligned} \partial_l \partial_k Q_{\mu\nu} \approx \frac{S_N}{2a} & \left[ \partial_l \tilde{\varphi} (p_{0\mu} \tilde{n}_{0\nu} + \tilde{n}_{0\mu} p_{0\nu} - p_{1\mu} \tilde{n}_{1\nu} - \tilde{n}_{1\mu} p_{1\nu}) \delta_{kx} \right. \\ & + (\partial_k \tilde{\varphi} \delta_{lx} + x \partial_l \partial_k \tilde{\varphi}) (p_{0\mu} \tilde{n}_{0\nu} + \tilde{n}_{0\mu} p_{0\nu} - p_{1\mu} \tilde{n}_{1\nu} - \tilde{n}_{1\mu} p_{1\nu}) \\ & + 2x (\partial_l \tilde{\varphi}) (\partial_k \tilde{\varphi}) (p_{0\mu} p_{0\nu} - p_{1\mu} p_{1\nu}) \\ & + \partial_l \tilde{\varphi} (p_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{0\mu} p_{1\nu} + p_{1\mu} \tilde{n}_{0\nu} + \tilde{n}_{1\mu} p_{0\nu}) \delta_{ky} \\ & + (\partial_k \tilde{\varphi} \delta_{ly} + y \partial_l \partial_k \tilde{\varphi}) (p_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{0\mu} p_{1\nu} + p_{1\mu} \tilde{n}_{0\nu} + \tilde{n}_{1\mu} p_{0\nu}) \\ & \left. + 2y (\partial_l \tilde{\varphi}) (\partial_k \tilde{\varphi}) (p_{0\mu} p_{1\nu} + p_{1\mu} p_{0\nu}) \right] \end{aligned} \quad (7)$$

Evaluated at  $x = y = 0$  (i.e. the disclination core) this becomes:

$$\partial_k Q_{\mu\nu} \approx \frac{S_N}{2a} [(\tilde{n}_{0\mu} \tilde{n}_{0\nu} - \tilde{n}_{1\mu} \tilde{n}_{1\nu}) \delta_{kx} + (\tilde{n}_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{1\mu} \tilde{n}_{0\nu}) \delta_{ky}] \quad (8)$$

and for the higher order derivatives:

$$\begin{aligned} \partial_l \partial_k Q_{\mu\nu}|_{x=y=0} \approx \frac{S_N}{2a} & \left[ \partial_l \tilde{\varphi} (p_{0\mu} \tilde{n}_{0\nu} + \tilde{n}_{0\mu} p_{0\nu} - p_{1\mu} \tilde{n}_{1\nu} - \tilde{n}_{1\mu} p_{1\nu}) \delta_{kx} \right. \\ & + \partial_k \tilde{\varphi} (p_{0\mu} \tilde{n}_{0\nu} + \tilde{n}_{0\mu} p_{0\nu} - p_{1\mu} \tilde{n}_{1\nu} - \tilde{n}_{1\mu} p_{1\nu}) \delta_{lx} \\ & + \partial_l \tilde{\varphi} (p_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{0\mu} p_{1\nu} + p_{1\mu} \tilde{n}_{0\nu} + \tilde{n}_{1\mu} p_{0\nu}) \delta_{ky} \\ & \left. + \partial_k \tilde{\varphi} (p_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{0\mu} p_{1\nu} + p_{1\mu} \tilde{n}_{0\nu} + \tilde{n}_{1\mu} p_{0\nu}) \delta_{ly} \right] \end{aligned} \quad (9)$$

Note that this matches Cody's Eq. (7.5) for  $k = l$ :

$$\begin{aligned} \partial_k \partial_k Q_{\mu\nu}|_{x=y=0} \approx \frac{S_N}{a} & \left[ \partial_k \tilde{\varphi} (p_{0\mu} \tilde{n}_{0\nu} + \tilde{n}_{0\mu} p_{0\nu} - p_{1\mu} \tilde{n}_{1\nu} - \tilde{n}_{1\mu} p_{1\nu}) \delta_{kx} \right. \\ & \left. + \partial_k \tilde{\varphi} (p_{0\mu} \tilde{n}_{1\nu} + \tilde{n}_{0\mu} p_{1\nu} + p_{1\mu} \tilde{n}_{0\nu} + \tilde{n}_{1\mu} p_{0\nu}) \delta_{ky} \right] \end{aligned} \quad (10)$$

Before calculating the  $L_2$  term (which is ostensibly harder), we redo Cody's isotropic calculation to make sure everything works correctly. To simplify things, we note that Eq. (10) already has an explicit factor of  $\partial_k \tilde{\varphi}$  on every term, and so when we calculate  $\mathbf{g}$  to  $\mathcal{O}(\tilde{\varphi})$  we may take approximate

all other factors to  $\mathcal{O}(1)$ . In particular, this implies  $\hat{\mathbf{n}} \approx \hat{\mathbf{n}}$ . We use the following identities:

$$\begin{aligned}
\hat{\mathbf{n}}_0 \cdot \hat{\mathbf{n}}_1 &= 0 \\
\hat{\mathbf{n}}_0 \cdot \hat{\mathbf{n}}_0 &= \hat{\mathbf{n}}_1 \cdot \hat{\mathbf{n}}_1 = 1 \\
\mathbf{p}_0 \cdot \hat{\mathbf{n}}_0 &= \mathbf{p}_1 \cdot \hat{\mathbf{n}}_1 = 0 \\
\mathbf{p}_0 \cdot \hat{\mathbf{n}}_1 &= -\mathbf{p}_1 \cdot \hat{\mathbf{n}}_0 = \hat{\mathbf{q}} \cdot \hat{\mathbf{\Omega}} \\
\hat{\mathbf{\Omega}} \cdot \hat{\mathbf{n}}_0 &= \hat{\mathbf{\Omega}} \cdot \hat{\mathbf{n}}_1 = 0 \\
\hat{\mathbf{\Omega}} \cdot \hat{\mathbf{\Omega}} &= 1 \\
\hat{\mathbf{n}}_0 \times \hat{\mathbf{n}}_1 &= \hat{\mathbf{\Omega}} \\
\hat{\mathbf{\Omega}} \times \hat{\mathbf{n}}_0 &= \hat{\mathbf{n}}_1 \\
\hat{\mathbf{\Omega}} \times \hat{\mathbf{n}}_1 &= -\hat{\mathbf{n}}_0 \\
\mathbf{p}_0 \times \hat{\mathbf{n}}_0 &= -\hat{\mathbf{q}} + \hat{\mathbf{n}}_0 (\hat{\mathbf{q}} \cdot \hat{\mathbf{n}}_0) \\
\mathbf{p}_1 \times \hat{\mathbf{n}}_1 &= -\hat{\mathbf{q}} + \hat{\mathbf{n}}_1 (\hat{\mathbf{q}} \cdot \hat{\mathbf{n}}_1) \\
\mathbf{p}_0 \times \hat{\mathbf{n}}_1 &= \hat{\mathbf{n}}_0 (\hat{\mathbf{q}} \cdot \hat{\mathbf{n}}_1) \\
\mathbf{p}_1 \times \hat{\mathbf{n}}_0 &= \hat{\mathbf{n}}_1 (\hat{\mathbf{q}} \cdot \hat{\mathbf{n}}_0)
\end{aligned} \tag{11}$$

We calculate  $\hat{\mathbf{\Omega}} \cdot \mathbf{g}$  for the isotropic case in a Jupyter notebook and end up with Eq. (7.7) from Cody's thesis.

Now for the  $L_2$  terms we calculate:

$$\begin{aligned}
\partial_i \partial_k Q_{kj} \big|_{x=y=0} &\approx \frac{S_N}{2a} \left[ \partial_i \tilde{\varphi} (p_{0x} \tilde{n}_{0j} + \tilde{n}_{0x} p_{0j} - p_{1x} \tilde{n}_{1j} - \tilde{n}_{1x} p_{1j}) \right. \\
&\quad + \partial_k \tilde{\varphi} (p_{0k} \tilde{n}_{0j} + \tilde{n}_{0k} p_{0j} - p_{1k} \tilde{n}_{1j} - \tilde{n}_{1k} p_{1j}) \delta_{ix} \\
&\quad + \partial_i \tilde{\varphi} (p_{0y} \tilde{n}_{1j} + \tilde{n}_{0y} p_{1j} + p_{1y} \tilde{n}_{0j} + \tilde{n}_{1y} p_{0j}) \\
&\quad \left. + \partial_k \tilde{\varphi} (p_{0k} \tilde{n}_{1j} + \tilde{n}_{0k} p_{1j} + p_{1k} \tilde{n}_{0j} + \tilde{n}_{1k} p_{0j}) \delta_{iy} \right]
\end{aligned} \tag{12}$$

We may find  $\partial_j \partial_k Q_{ki}$  by just taking the transpose. The last term that we need is:

$$\begin{aligned}
\partial_l \partial_k Q_{kl} \big|_{x=y=0} &\approx \frac{S_N}{2a} \left[ \partial_l \tilde{\varphi} (p_{0x} \tilde{n}_{0l} + \tilde{n}_{0x} p_{0l} - p_{1x} \tilde{n}_{1l} - \tilde{n}_{1x} p_{1l}) \right. \\
&\quad + \partial_k \tilde{\varphi} (p_{0k} \tilde{n}_{0x} + \tilde{n}_{0k} p_{0x} - p_{1k} \tilde{n}_{1x} - \tilde{n}_{1k} p_{1x}) \\
&\quad + \partial_l \tilde{\varphi} (p_{0y} \tilde{n}_{1l} + \tilde{n}_{0y} p_{1l} + p_{1y} \tilde{n}_{0l} + \tilde{n}_{1y} p_{0l}) \\
&\quad \left. + \partial_k \tilde{\varphi} (p_{0k} \tilde{n}_{1y} + \tilde{n}_{0k} p_{1y} + p_{1k} \tilde{n}_{0y} + \tilde{n}_{1k} p_{0y}) \right]
\end{aligned} \tag{13}$$

Now we have to compute  $\hat{\mathbf{\Omega}} \cdot \mathbf{g}$ . Cody has already done this for the isotropic medium, we need to do it for the  $L_2$  term. Luckily  $\mathbf{g}$  is linear in  $\partial_t Q$  terms, so we first calculate:

$$\begin{aligned}
(\partial_i \partial_k Q_{kj}) (\partial_l Q_{mj}) &= \frac{S_N^2}{4a^2} \left[ \partial_i \tilde{\varphi} (p_{0x} \tilde{n}_{0j} + \tilde{n}_{0x} p_{0j} - p_{1x} \tilde{n}_{1j} - \tilde{n}_{1x} p_{1j}) \right. \\
&\quad + \partial_k \tilde{\varphi} (p_{0k} \tilde{n}_{0j} + \tilde{n}_{0k} p_{0j} - p_{1k} \tilde{n}_{1j} - \tilde{n}_{1k} p_{1j}) \delta_{ix} \\
&\quad + \partial_i \tilde{\varphi} (p_{0y} \tilde{n}_{1j} + \tilde{n}_{0y} p_{1j} + p_{1y} \tilde{n}_{0j} + \tilde{n}_{1y} p_{0j}) \\
&\quad + \partial_k \tilde{\varphi} (p_{0k} \tilde{n}_{1j} + \tilde{n}_{0k} p_{1j} + p_{1k} \tilde{n}_{0j} + \tilde{n}_{1k} p_{0j}) \delta_{iy} \left. \right] \\
&\quad \cdot [(\tilde{n}_{0m} \tilde{n}_{0j} - \tilde{n}_{1m} \tilde{n}_{1j}) \delta_{lx} + (\tilde{n}_{0m} \tilde{n}_{1j} + \tilde{n}_{1m} \tilde{n}_{0j}) \delta_{ly}] \\
&=
\end{aligned} \tag{14}$$

We note the following properties:

$$\begin{aligned}
\epsilon_{\gamma im} \delta_{ix} = \epsilon_{\gamma xm} &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} = \delta_{\gamma z} \delta_{my} - \delta_{\gamma y} \delta_{mz} \\
\epsilon_{\gamma im} \delta_{iy} = \epsilon_{\gamma ym} &= \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix} = \delta_{\gamma x} \delta_{mz} - \delta_{\gamma z} \delta_{mx}
\end{aligned} \tag{15}$$
